The smoke-EL system is composed of three components. Once installed in your model, each individual piece will work harmoniously with the other pieces to produce a thick white smoke. The smoke can be activated manually or automatically by using the built-in acceleration sensor. All the important data will be transferred via telemetry and will be displayed at your transmitter.

You will be the star at the air show with Smoke-EL system! The smoke effect will highlight your maneuvers in a truly unprecedented way. The G-sensor activates and deactivates the smoke synchronous to your flight.

The SmokeDriver
A high-performance microprocessor controls and supervises the smoke system.

The SmokeDriver is connected to the RC system via one free channel. Depending on the version, batteries with 6s-10s cells or 12s-14s cells can be used.

The integrated supervision will turn off the system as soon as voltage drops below 3.3 volt/cell. The built-in G-sensor is operational at 0-7g and can therefore be easily customized to your model and flying style.

Telemetry is available for all common RC-systems.

The Evaporator
The smoke is produced in these pipes. You will need a cable and a tube to connect them. The pipes are extremely lightweight at 130g and we offer an assembly set for easy attachment to your model.

The SmokePump
This 90g lightweight pump delivers our specially developed oil (RedOil) to the evaporators. Simply connect the pump to the SmokeDriver and then regulate output via the transmitter.
